TEST

MASTG-TEST-0295: **GMS Security Provider Not Updated**

Overview

This test checks whether the Android app ensures the Security Provider is [updated to mitigate SSL/TLS vulnerabilities](#). The provider should be updated using Google Play Services APIs, and the implementation should handle exceptions properly.

Steps

- Reverse engineer the app ([Decompiling Java Code](#)).
- Use static analysis ([Static Analysis on Android](#)) to search for usage of `ProviderInstaller.installIfNeeded` or `ProviderInstaller.installIfNeededAsync`.

Observation

The output should list all locations where the Security Provider update is performed and how exceptions are handled (for `installIfNeeded`), or how the `ProviderInstallListener` handles errors (for `installIfNeededAsync`).

Evaluation

The test fails if the app does not update the provider, or it does not handle exceptions properly. Check that these calls occur before any network connections are made.
